Alzheimer and other neurological disease patient-specific neuron cell development

Alzheimer and other neurological disease patient-specific neuron cells are generated by fusion of functionally enucleated cytoplasmic donor neuronal progenitor cell line with valproic acid treated fibroblasts and/or PBMNC obtained from clients. These patient-specific epigenetically induced disease-specific neuron cells are characterized for many neuron specific-functions. These patient-specific neuron cells will be a great tool to understand many biological mechanism of neurological disease processes. These cells will also be useful for drug development applications.
